AUTHOR: Froyshteter, G.B., Candidate of Technical Sciences

TITLE: Determining the Resistance of a Burning Layer of Fuel
(K Voprosu ob opredelenii soprotivleniya goryashchego sloya topliva)

PERIODICAL: Teploenergetika, 1959, Nr 5: pp 50-55 (USSR)

ABSTRACT: The aero-dynamic properties of cold layers of fuel have been extensively studied but little work has been done on burning layers of fuel. The test rig illustrated diagrammatically in Fig 1 was set up to make such a study. The fuel burned in a cylindrical furnace of 250 mm diameter; during the experiments the height of the fuel layer was maintained constant and equal to the height of the oxygen zone, which was determined in advance for each type of fuel. The methods of making the various measurements are explained. The fuels used in the tests were "thermo-anthracite" and coke with four sets of particle sizes ranging between 15 to 25 mm and 5 to 7 mm. The main difference between the fuels lay in the ash content and the ash melting-point. Special tests

Card 1/4

SOV/96-59-5-9/19

Determining the Resistance of a Burning Layer of Fuel

influence on the aerodynamics of the layer but when coke was burned a slag layer formed, complicating the conduct of the experiments. The ideal theoretical case of burning a layer of particles of uniform size is considered. In particular, formula (5), for the fractional composition of the burning layer, is compared with the experimental curves in Fig 2. Agreement is good, indicating that the relationships used in deriving expression (5) are valid. Experimental data on the porosity of the burning layer for various fractions and conditions are tabulated in comparison with analogous data for a cold layer. It will be seen that the porosity is practically the same in the two cases. An analytical solution of the resistance of a burning layer is based on experimental data about particle size distribution in the height of the layer and the temperature distribution of the gas flow in the layer. The assumptions that are made in the calculations are explained and expression (6) is derived for the resistance factor of the burning layer.

Card 2/4

This factor is plotted as function of the Reynolds number

SOV/96-59-5-9/19

Determining the Resistance of a Burning Layer of Fuel

in Fig 3, on which experimental results are also plotted. The agreement must be considered satisfactory in view of the complexity of the combustion process in the layer. Graphical comparison of the resistance function for hot and cold layers in Fig 3 shows that the equations are similar in the two cases but the numerical coefficients differ. Therefore, experimental data obtained in a cold layer can be used to determine the nature of the relationship between the resistance and the Reynolds number in a hot layer. However, the actual values of resistance factors for hot and cold layers are very different, mainly because of the differences in the temperature conditions and changes in layer structure. Results derived from representing the same process by a model in which sodium chloride is dissolved in water are very briefly mentioned. A practical formula for calculation of the resistance of the burning layer based on the theoretical analysis and the test data is offered as Eq (7). Here all the terms are known from the initial

Card 3/4

SOV/96-59-5-9/19

Determining the Resistance of a Burning Layer of Fuel

condition except the resistance factor term, which is given by expression (8). The accuracy of the proposed method of determining the resistance of a burning layer may be judged from Fig 4, where the theoretical curve is compared with experimental data obtained in 58 tests. In 75% of the cases the error is not greater than 10% and the mean square error is 8.78%. The formulae given are valid if the height of the burning layer does not exceed the height of the oxygen zone: they are only approximately valid for the reducing zone. If a reducing zone is present, the mean temperature should be determined for each zone separately and a mean value determined for the entire layer, making allowance for the height of each zone. There are 4 figures and 5 references, 4 of which are Soviet and 1 English.

Preparation of a lead-sodium alloy by electrolysis of molten sodium hydroxide. Al. Turassy and M. Fruchter. Rev. chim. (Bucharest) 9, 203-6 (1958) (English summary). Electrolysis with agitation at 350-70° of molten NaOH (<30%)Na₂CO₃ in a cell by using Ni anodes (2.8 sq. cm.) and molten Pb cathode (104 sq. cm.) gave Pb-Na alloys with various Na contents depending on conditions. In a continuous pilot cell operated to produce an alloy contg. 5% Na, the c.d. was about 80 amp./sq. cm., the power consumption was 12.5 kw./kg. Na, and the consumption of NaOH and Na₂CO₃ was 2.25 kg. of each kg. of Na.

AUTHORS: Antonescu, A., and Fruchter, M. Engineers

TITLE: Electrothermal production of Al-Si alloy from indigenous kaolin

PERIODICAL: Revista de chimie, v. 12, no. 3, 1961, 150-156

TEXT: The authors investigated the structural, technological and economic factors affecting the electrothermal production of Al-Si alloy from indigenous kaolin and charcoal. In doing so, they had in view the subsequent separation of aluminum from this alloy by processes which have been recently studied. The experimental results were considered satisfactory in order to start production of the alloy on a semi-industrial scale. A review of the thermodynamics and kinetics of the specific reactions involved indicated the following preliminary requirements. (a) Rapid heating of the charge up to 2100°C, requiring a furnace with high specific power input; (b) very pure raw materials;

Card 1/4

Electrothermal production...

27002

R/003/61/012/003/003/004

D238/D302

(c) effectuating the reduction in the solid and gaseous phases only;
 (d) speedy removal of the alloy and gases from the reaction zone; and
 (e) a carefully proportionated and granulated charge. The 60 KW furnace was operated with a 380 V single phase transformer. The maximum intensity was 600A at 35-40V. The volume of the working space was calculated from the energy consumption between two consecutive drainings, corresponding to a production of 6.8 kg of alloy; a volume of 46 dm³ was obtained. The stagnation period was 2.25 hours. The bottom electrode, made of graphitized carbon, had a current density of 2.27A/cm²; the corresponding figure for the top electrode was 20.4 A/Cm² and the medium - 6.85 A/cm². The specific productivity was 940Kg/m²/24 hours. Charges were made of washed kaolin (SiO₂, 52.61%; Al₂O₃, 33.67%; Fe₂O₃, 1.32%; moisture 11.11% etc.) and charcoal (C₁ 79.63%; ashes. 5.35%; volatile matter, 15.04%, etc.) The optimum charge was made with 1% of C in excess of the theoretical requirements. The components were dried, ground, sieved, mixed and pelletised (using 30% of H₂O b.w.). The

Card 2/4

D238/D302

Electrothermal production...

optimum tension and current intensity were found as 40V and 1600 A, respectively. A rapid method for analysis of the alloy was elaborated. The sample is treated at 900°C with dry, gaseous HCl to chlorinate the metals, which are then separated as chlorides and analyzed by known methods. The washed residue is then oxidized at 1000 C and CO₂ is trapped by KOH solution, giving the amount of free carbon. Next, PbO is added and another oxidation at 1000°C destroys the carbides. Si is determined by difference. The power consumption per unit of product is shown to be a function of furnace power. A specific consumption of 18.6-22.6 kWh/Kg alloy was attained at 40V and 1600A. This figure is identical with the specific consumption for a 250kWh-furnace, given by literature. The consumption of kaolin, charcoal and electrodes per Kg of alloy was 3.63, 1.68 and 0.05 Kg. respectively. (8) Yields of 56 to 80% were recorded. Most of the losses are attributed to volatilization of a.c.; the losses were exceedingly high due to the relatively wide space between electrodes and walls. Alloys of the following composition were produced. Al, 34-36%; Si 56-57%; Fe 4-7%; Ca, traces;

Card 3/4

Electrothermal production...

27002 R/003/61/012/003/004
D238/D302

carbides 2-3%; oxides 0.3%. The high actual ratio of Si to Al is attributed to volatilization of the latter; the high Fe content is probably due to contamination from working tools and from the wall bricks. The carbide content is well within the permissible limit of 6%. The cost of the combined production of Si and Al by this process is comparable with that of producing these elements separately by the older methods; i.e. Al from bauxite and Si from quartz. There are 2 figures and 4 tables.

TITLE: Extracting germanium concentrate from the ammonia liquor of coking plants

PERIODICAL: Revista de Chimie, v. 12, no. 9, 1961, 508-511

TEXT: The article describes experiments conducted on the precipitation of germanium with tannin from ammonia liquor. Precipitation was achieved by mixing 1-1.5 lit of ammonia liquor with a solution of 5% tannin and 17% FeCl_3 . The mixture was agitated for 10 minutes and decanted. After 24 hours, 3/4 of the total quantity was syphoned and analyzed to establish the quantity of non-precipitated germanium. A 90% precipitation yield at a concentration of the final solution below 0.1 g Ge/cu m was obtained by heating the solution to 80°C and simultaneously reducing the pH value to 2-2.5 and adding 50 g tannin/g Ge. Due to the very low percentage of germanium concentration in ammonia liquor, heating to 80°C and reducing the pH are no longer economical. Thus, a series of experiments have been conducted by varying the precipitation factors. The solutions used had an

Card 1/4

Extracting germanium concentrate 27003

R/003/61/012/009/002/008
D019/D105

initial concentration of 14 kg NH_3 /cu m and 2.6 g Ge/cu m at pH 8. Precipitation was carried out at 20°C, with 100 g tannin and 200 g Fe^{3+} per g of Ge, in a solution with pH 8. It was found that within the initial concentration of 0.17-2.6 g Ge/cu m, the efficiency of tannin, i.e. the precipitation yield, was practically constant, with the final solutions reaching a concentration of <0.1 g Ge/cu m. The precipitates contained ~ 200-300 g/t Ge, but after calcining the content increased to 600-700 g/t. The precipitation yield of germanium did not exceed 60% when 100-200 g tannin/g Ge were added. To determine the size of precipitation granules, two series of tests were carried out. One series of tests which was carried out by filtering a mixture of tannin and ammonia liquor with a no. 3 Gooch filter and filter paper, established the variation in size as dependent on time. After 120 hours of agitation, the total germanium was included in granules, the size of which exceeded 20 - 30 μ . The second series of tests was carried out by agitating the mixture of ammonia liquor and tannin for only 10 minutes, followed by decantation. After 72 hours the granules showed a yield of 65% while with continuous agitation for 72 hours the yield was ~ 80%. Coagulation and separation of particles took a little less time in case of con-

Card 2/4

27003

R/003/61/012/009/002/008
D019/D105

Extracting germanium concentrate

tinuous agitation. By centrifugation for 15 minutes at 1,700 rpm, the result was similar to that achieved with 5 days of mechanical agitation or with over 7 days of decantation. The separation of germanium amounted to 80% in case of analysis of a clear solution obtained in a test tube by centrifugation, and to 98% when the solution was filtered prior to the analysis. Precipitation with tannin of germanium from ammonia liquor includes (a) partial coprecipitation of ferric ions and germanium in an alkaline medium and their immediate separation once the reaction has begun and (b) colloidal-type reaction of tannin with germanium, leading to the formation of insoluble compounds. Conclusions: (1) addition of 100 g of tannin and 200 g of iron/g Ge from ammonia liquor is sufficient; (2) a filter of particular fineness should be used in separating the precipitate; (3) solutions should be mixed as thoroughly as possible; (4) separation of ~70-80% of germanium may be achieved within 1-2 hours by mechanical agitation, followed by filtering through a 20-30- μ filter; (5) products containing tannin may be used instead of pure tannin and (6) the average composition of germanium precipitates obtained from ammonia liquor with a content of ~1 g/Ge cu m is: C, 16.7%, Pb, 0.021%, Cu, 0.01%, Zn, 0.95%, SiO₂, 0.39%, Al₂O₃, 2.02%, Fe, 15.3% and Ge, 0.02%. TITLE: Antimony extraction from the anodic mud obtained from the electrolytic refining of decoppered crude lead₁

SOURCE: Revista de chimie, v. 16, no. 8, 1965, 352-358

TOPIC TAGS: antimony, metal extracting, electrolytic refining, lead

ABSTRACT: The authors describe a method for the electrolytic processing of the anodic muds resulting from the electrolytic refining of crude lead. The electrolyte consists of antimony fluoride and buffers, and the cell of the diaphragm type -- pure antimony is deposited at the cathode. The antimony extraction yield is over 90 percent, and the remaining metals are easily extractable from the secondary mud. Orig. art. has: 2 figures and 7 tables.  Title : New Reservoirs of *L. grippotyphosa*
 Ustav epidemiologie a mikrobiologie v Praze, reditel Prof. Karel Raska
 Orig Pub. : Ceskosl. Epidemiol., Mikrobiol., Imunol., 1957,
 Vol.6, No.6, 361-364
 Abstract : In northwestern Czechoslovakia leptospira were isolated from the kidneys not only of the field mouse *Microtus arvalis* but also from the kidneys of *M. agrestis*, *Clethrionomys glareolus*, *Apodemus flavicollis*, *Apodemus sylvaticus* and *Mus musculus*. All isolated strains were determined as *Leptospira grippotyphosa*. Discovery of the latter in *Mus musculus* compels the author to the idea that infection with these leptospira may occur not only in field mice but also under domestic conditions. The same pertains to the above-mentioned species of mouse-like rodents, which migrate in the winter to human habitation sites. - Z.A.Yakubovich

The thianthrene series. I. Thianthrene β -sulfonic acid disulfone. V. V. Kozlov, Ye. P. Fruktova and O. M. Shemyakina. *J. Gen. Chem.* (U. S. S. R.) 10, 1077 (1940). PCl_5 , CaH_2 and AlCl_3 give 78.5% thianthrene which is oxidized by CrO_3 in glacial HOAc to give 92% thianthrene disulfone (I), m. 321°. This is very inert toward sulfonating agents, and only when heated for 2 hrs. at 140° with a large excess of 62% oleum in a sealed tube does it give 58% of a monosulfonic acid, isolated as the K salt (II). No other compds. can be obtained. The NH, Mg, Na, K, Cu, Ba, Zn, Al, Fe, Pb and Ag salts are described. When II is refluxed for 5 hrs. with PCl_5 at 100° in the presence of a little POCl_3 , it gives 77% of the sulfonyl chloride (III), decmp. 191°. When III is heated with H_2O in a sealed tube, it gives a very hygroscopic acid. III and NH, give the corresponding acid amide, m. 178°. When II is ground with PCl_5 and some POCl_3 and heated for 5 hrs. at 180°, it gives 78% of a chlorothianthrene disulfone, m. 120°, which is identical with the compd. prepd. by oxidizing β -chlorothianthrene with CrO_3 in HOAc. Fusion of II with NaOH gives PhOH, resorcinol and $p\text{-HOCH}_2\text{SO}_3\text{H}$. These facts prove that sulfonation of I occurs in the β -position. H. M. L.

TITLE: Color Reactions for Distinguishing Lanthanum From Cerium (Tsvetnyye reaktsii dlya otlichiya lantana ot tseriya)

PERIODICAL: Tr. po khimii i khim. tekhnologii, 1958, Nr 1, pp 132-133

ABSTRACT: La produces an orange coloring with acid monochrome bordeaux C (I). Ce^{4+} and Ce^{3+} do not produce any color. Detectable minimum of La is 1.5 γ /cc, minimum concentration is 1:660,000. Al, Be, Ca, Ti, Th, UO_2^{2+} , and Fe^{3+} , which also produce a yellow and orange coloring with I, impede the determination. The method is applicable for the colorimetric microtitration of La in dilute solutions of its salts. It is feasible to determine 2 - 10 γ /cc La by the standard-series method with 12.5% maximum error. In the presence of Ce^{3+} galleanphthalein produces a blue or violet color. The detectable minimum is 1/2 γ /cc Ce^{3+} , the minimum concentration is 1:800,000 at pH 11.4. With other pH values the reaction is less sensitive. Phosphates, La (258 γ /cc), and salts of Nd and Pr impede the reaction. The reaction can be used for the quantitative determination of Ce by the standard-series method.
